Abstract

It has been reported that hyperuricemia might be responsible for cardiovascular diseases as well as gout and renal injury. Hypertension and hyperlipidemia, which are also responsible for cardiovascular diseases, are often associated with hyperuricemia. Thus, the treatment of hypertension and hyperlipidemia associated with hyperuricemia is also important. Losartan, an antihypertensive agent, and fenofibrate, an antihyperlipidemic agent, are known to have uric acid lowering effects. Both agents are useful for hyperuricemia with associated with hypertension and hyperlipidemia. In this section, we reported the characteristics and usefulness of these two agents in hyperuricemic patients with hypertension and hyperlipidemia.
